

Introduction

Calculus is widely used for calculating the building's heat loss, areas and masses of difficult geometric form structures, for minimizing or maximizing areas of designed structures.

What is calculus?

The branch of mathematics that deals with the finding and properties of derivatives and integrals of functions, by methods originally based on the summation of infinitesimal differences. The two main types are differential calculus and integral calculus. Basically it is branch of mathematics concerned with the calculation of instantaneous rates of change (differential calculus) and the summation of infinitely many small factors to determine some whole (integral calculus).

Where is it used?

1. **Finance** (Statisticians, Credit card companies, etc)
2. **Chemistry** (Inorganic Chemistry: The Rate of Reaction)
3. **Biology** (Study of Population)
4. **Physics** (Mechanics)
5. **Other Fields** (Electrical Engineering, Architect, Space flight engineers, Graphic artist)

What is Architecture ?

- Definition: The style of design and method of construction of buildings and other physical structures.
- Architecture is both the process and the product of planning, designing, and constructing buildings or other structures. Architectural works, in the material form of buildings, are often perceived as cultural symbols and as works of art. Historical civilizations are often identified with their surviving architectural achievements.
- Architecture began as rural, oral vernacular architecture that developed from trial and error to successful replication. Indian and Chinese architecture influenced forms all over Asia and Buddhist architecture in particular took diverse local flavors.

How is it used?

In designing structures, an architect must visualize the solutions to both functional and aesthetic problems – balancing art with science and math. There are architecture math requirements - calculus - so that an architect can understand the forces acting on the structures she designs. It also gives her a means of calculating factors such as heat loss over time. This understanding must be mathematically precise if the structures architects design are to be stable and safe for use.

External architecture

Calculus is also used by architects in plotting buildings, bridges, hotels, gardens, etc.

Architectural design optimisation is a subfield of engineering that uses the method of optimisation to aid and solve architectural design problem..

Differential calculus is used to determine the maximum or minimum value of certain objects, such as the window size, air duct space, etc. This translates to figuring out the biggest possible size for a window, or finding the smallest possible space that an air duct can maintain. Differential calculus can also be used to determine the maximum amount of material an architect can get for the cheapest price or to find the balance between weight and strength of a material.

Example

The Eiffel Tower

Designed by Gustave Eiffel, the Eiffel Tower is one of the most famous examples of calculus in architecture because of its many curves, yet very solid structure.

The Calculus!

The Eiffel Tower in a differential equation:

This is the width of the Eiffel Tower as a function of the distance from top.

The Eiffel Tower in differential equation:

$$a \cdot f(x) \cdot \int_0^x f(t)^2 \cdot dt = x \cdot \int_0^x f(t) \cdot dt - \int_0^x f(t) \cdot t \cdot dt$$

This is the width of the Eiffel Tower as a function of a distance from the top.

Skyscraper

- Definition: The structural definition of the word “*skyscraper*” was refined later by architectural historians, based on engineering developments of the 1880s that had enabled construction of tall multi-storey buildings. This definition was based on the steel skeleton—as opposed to constructions of load-bearing masonry, which passed their practical limit in 1891 with Chicago's Monadnock Building.
- A **skyscraper** is a tall continuously habitable building having multiple floors. Modern sources currently define skyscrapers as being at least 100 metres or 150 metres in height, though there is no universally accepted definition. Skyscrapers are very tall high-rise buildings. Historically, the term first referred to buildings with between 10 and 20 stories when these types of buildings began to be constructed in the 1880s. Skyscrapers may host offices, hotels and residential spaces.

Many factors come into play when an architect designs a building. Aesthetics, lighting, size, and even heating are taken into consideration. If an architect is focusing on the heating of his/her structure and wants to figure out how much heat is being lost based on temperature variations throughout the day, they can utilize calculus. They can graph heat loss vs. time and find the area under the curve. This area can be found by evaluating a definite integral and finding the area between the curve and the x-axis.

THE HEIGHT OF TECHNOLOGY

CONCRETE TECHNOLOGY

Provides stronger and more rigid concrete than used in the past, reducing construction costs and freeing interior space.

THINNER-THIN STEEL FIBERS

Enhance a concrete column's stiffness and durability.

SMART FIBERS AND CARBON NANOTUBES

Increase compressive strength beyond 200 megapascals and relay information about the state of the concrete structural members to a building's operations center. They also improve fire and blast resistance.

ELEVATOR TECHNOLOGY

Provides over more capacity while using less of a building's footprint.

CHANGING LANES

Lets multiple cars operate in the same shaft. Old Elevator's Otisway system's cars sit in metal frames that are raised and lowered inside a hallway. When one car needs to go around another, a small electric motor propels it horizontally to a different frame.

GREEN TECHNOLOGY

Aims for zero net energy use. Elevators, lights, and automated building monitoring systems will operate without drawing power from the grid.

WINDMILLS

Transform wind from a problem to a solution.

PHOTOVOLTAIC PANELS

Allow a building to absorb energy through its skin.

DOUBLE-LAYER FACADES

Reduce the amount of energy needed to maintain comfortable temperatures in apartments or offices.

SAFETY TECHNOLOGY

Design escape from a 300th-floor office into the realm of possibility.

COLLAPSIBLE ESCAPE PODS

Are capable of carrying 150 people at a time. They swing out from their rooftop storage pods, descend to the ground, expand into the car units, and ascend to pick up evacuees.

REFUGER FLOORS

Offer shelter, medical, chemical, and gas-resistant safe havens to people who can't reach the lobby.

ELECTROMAGNETIC SHAFTS

Located at each of a building's corners, the shafts are dotted with electromagnets that provide controlled descent for evacuees wearing metal-studded vests.

The role of system integration in the design of sustainable skyscrapers

Relation of architecture and calculus.

The familiar hyperbolic curves math students learn in calculus class are just one example of how this branch of mathematics is important in architecture. Famous landmarks, such as the Gateway Arch in St. Louis and the dome of St Paul's Cathedral in London, both incorporate hyperbolic curves called catenaries into their design. When you hold a slack chain between two hands you will recognize this curve if. A catenary arch can support the weight of a structure with a minimum amount of material.

Calculus in Ancient Architecture.

The most remarkable ancient architecture of all may be the pyramids of Egypt, constructed between 2700 B.C. and 1700 B.C.

The accuracy in the construction of the pyramids in ancient Egypt is evidence of the mathematical, especially geometrical, knowledge that they possessed. They were able to apply the principles of right triangles well, which is evidenced by the accuracy of the pyramid corners at the base—a maximum error of 3'33"

The Golden Ratio

The Golden Ratio still serves as a basic geometric principle in architecture. You could even call it a timeless archetype, as it evokes in human beings a universal sense of harmony when they see or stand in a building designed with this principle. And perhaps not surprisingly, we see the Golden Ratio demonstrated throughout “architectures” of the natural world

Blueprints.

Calculating ratio is essential, as well, when it's time to construct a building from the architectural blueprints. For example, it's important to get the proportions right between the height and length of a roof. To do that, building professionals divide the length by the height to get the correct ratio.

A Lack of Calculus

A well known example of neglect towards the calculus is the Leaning Tower of Pisa. The building was intended to stand straight, but the weight of the structure was not taken into consideration. Therefore, over time the building began to sink and lean over.
